

Insider QA Bootcamp | Final Project

Author: Ege Bozdemir

Submitted: 25.03.2024

Project Requirements:

<https://github.com/insiderqabootcampefinalproject/project-requirements>

Github Repository:

<https://github.com/insiderqabootcampefinalproject/insiderbootcampproject-egebozdemir>

Grafana Dashboard:

<https://snapshots.raintank.io/dashboard/snapshot/rrXXPHLmrXQkWZ06rvlY7ALzRjKTTWEQ>

1. Tech Stack

Java | Selenium | Maven | TestNG | MySQL | Jenkins | Grafana

Selenium - Java (21) Test Automation project with TestNG framework is created to fulfill the requirements. Created as a Maven project to enhance the dependency management and build automation. As Selenium, TestNG, Webdriver Manager, Jackson Databind, Extent Reports, Mysql Connector dependencies are injected, Maven Surefire plugin is also used.

2. Solution Overview

a. Architecture

- Code base is maintained in github repository
- Jenkins CI/CD pipeline is configured to trigger builds by push events/PRs fired in github project repository
- Jenkins build takes stage by Maven command which executes the test suite within the surefire plugin configuration at root pom.
- Results of the test cases executed are stored in the local mysql instance or generated on a html report based on the suite selection.
- Grafana dashboard is created for monitoring the metrics based on the results stored in database

b. Framework Design - Capabilities

- Maven structured framework with all necessary automation dependencies managed.
- Page Object Model design to drive locators from respective classes. Object creation within Page object classes encapsulated from Tests.
- Base Test factory class to set browser configurations on Global properties

- Test strategy applied by appropriate annotations to decide how tests should be clubbed and distributed.
- TestNG runner file to trigger tests with one single point of execution control
- Categorized tests with different tags of execution
- Data driven testing & parameterization using TestNG Data provider, HashMap and Json file readers
- Soft and Hard Assertions implemented in tests
- TestNG listeners with ITestResult interface implemented to capture screenshot on automated test failures and logging
- Database controller and listener to store test results in MySQL database
- Extent Report wrapper to generate excellent HTML reports
- Supports parallel test execution with thread safe mechanism (currently only with ExtentReport Listener, will be fixed for Database Listener also)
- Running the framework tests with Maven commands
- Integrated with Jenkins with Build Pipeline Jobs and triggers for Github events
- Customized Grafana dashboard to perfectly visualize the test results and tracking metrics

c. Useful Information

- Parallel test execution is supported for suites with 'ExtentReportListenersNG' currently due to the race condition issue occurring on Database operations when trying to run parallel tests. For parallel test execution, run 'ParallelSuiteExtentReport.xml'.
- Both options for generating html reports or storing test results on a database is available. You can find the generated html and screenshot files under '/reports' directory when you run tests on your local machine (run:'ParallelSuiteExtentReport.xml')
- To connect your database, edit 'DB_URL', 'USER', 'PASS' static variables with your own values in the Database Controller class. Be aware that you need to create the table in your db based on the logic followed.
- JSON test data file containing both valid and invalid test data for positive/negative flows added. With the data provider method in the 'BootcampTest', it's looping the same test with both data.

```

1 egebozdemir
@DataProvider
public Object[][] getData() throws IOException{
    //calling getJsonDataToMap inherited from BaseTest to get List of Hashmaps as test data
    List<HashMap<String,String[]>> data = getJsonDataToMap( filePath: System.getProperty("user.dir")+"/src/test/java/useinsider/Data/BootcampTask.json");
    return new Object[][] { {{data.get(0)}, {data.get(1)}}; //second test data (invalid) to showcase failed case
}

```

```

- MySQL database is created with single 'testresults' table inside. Each test run result is stored as new values to the table. Screenshot is taken for only failed cases and stored as png images, so for passed cases it's passed as null.

The screenshot displays a MySQL database interface with a 'testresults' table. The table contains columns: caseName, caseClass, caseStatus, caseStackTrace, caseDuration, and caseScreenshot. The data shows various test cases, some of which have failed, with corresponding screenshots stored in the caseScreenshot column. A 'Browse Open Positions' overlay is visible on the right side of the screen, featuring a search bar and filters for location and duration. The overlay also displays the text 'Data Length: 387258 bytes' and a 'Save...' button.

- Jenkins Pipeline is created and configured to trigger builds when any push events to repo/PR with stages defined in the Jenkinsfile present in the repo.

- Grafana dashboard is created by connecting the data source with MySQL plugin. Customized views for some of the stats are made. Dashboard snapshot is published as public via Grafana free service.
